

Abstract

Cyber-attacks are becoming more frequent and sophisticated, making it important to identify malicious activities before they can cause serious damage. **HNCAD (Multi-Protocol Honeypot Network for Cyber Attack Detection and Threat Intelligence)** is a cybersecurity system designed to detect, monitor, and analyze suspicious activities by attracting attackers to controlled and isolated environments called honeypots. The system supports multiple network protocols, allowing it to observe different types of attack attempts and collect useful information such as source addresses, connection details, commands, and attack patterns.

The collected data is analyzed to identify potentially malicious behavior and generate meaningful threat intelligence. By recording attacker interactions instead of allowing them to reach real systems, HONV provides a safe environment for studying cyber threats. The project also helps security teams understand common attack techniques and improve their defensive strategies. The proposed system combines honeypot technology, network monitoring, data collection, and threat analysis into a single platform. Overall, HONV provides a simple, practical, and scalable approach to cybersecurity monitoring and helps organizations better understand and respond to emerging network threats.
